## Outline

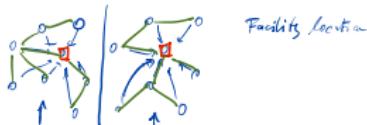

1. Minimum spanning trees

## The problem

- Undirected graph  $G = (V, E, c)$  with costs  $c : E \rightarrow \mathbb{R}_+$
- Definition:** A **spanning** subgraph is one that connects all vertices.
- Want:** Minimum cost spanning subgraph.
- Observation:** This must be a tree.  
Suppose we have a **cycle**: we can remove an edge, and the graph stays connected. We end up with a connected, cycle-free graph, by definition a tree.
- Thus: we can focus on minimum spanning trees.
- If the graph is **connected**: application to all components yields a **minimum spanning forest**.

Tree (acyclic graph)  $T_1 = (V_1, E_1)$   
Forest : collection of trees  $T_2 = (V_2, E_2)$

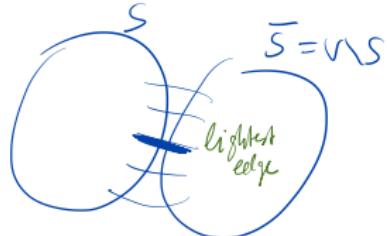

- Observation:** Reduction to a tree fails when we have negative costs.
- For negative costs the minimum cost spanning subgraphs could contain all edges! *Alg. with even w/ neg. atm costs*
- On the other hand: when we require trees, we have exactly  $n - 1$  edges, and every monotone transformation of the costs maintains minimality.
- In particular: linear transformations, and even more particular: addition of a constant.
- Thus: we can assume non-negative costs on trees.

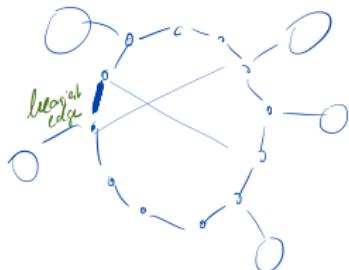

$$\begin{aligned}
 & \text{MST} \quad f(c) = c + 10 \\
 & f(c) = \tilde{c}(T^*) \\
 & c(T^*) = \tilde{c}(T^*) \\
 & \text{HST } T^* - (u, v) \\
 & \text{MST } T^* - (u, v) \\
 & c(T^*) = \tilde{c}(T^*) \\
 & \tilde{c}(T^*) = x \\
 & f(x) = x + c \\
 & \log \left( \prod_{e \in T} c_e \right) = \sum_{e \in T} \log c_e \\
 & \tilde{c}(T^*) = n - 1 \\
 & \tilde{c}(T^*) \leq \tilde{c}(T') \quad \forall T' \\
 & c(T^*) \leq c(T') \quad \forall T' \\
 & c(T^*) = \tilde{c}(T^*) \\
 & c(T^*) = n - 1
 \end{aligned}$$

- We can assume that all edge costs are different.
- All algorithms will work when edge costs are the same.
- Argument: by **perturbation** of the costs.

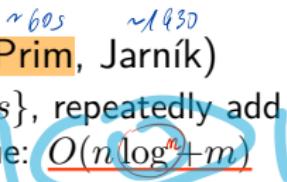

**Cut property** For every cut  $(S, \bar{S})$ : the lightest cut edge is part of the MST

**Cycle property** For every cycle  $C$ : the heaviest cycle edge is not part of the MST

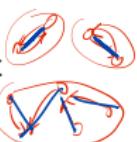

- Grow a component  $S$  (Prim, Jarník)
  - Starting from  $S = \{s\}$ , repeatedly add lightest  $(S, \bar{S})$ -edge
  - Using a priority queue:  $\cancel{O(n \log^m + m)}$
- Merge components (Kruskal)
  - Starting from sets  $\{v\}$  for all  $v \in V$ , process edges in ~~increasing~~ non-decreasing cost, add edges that connect components
  - Using a union/find data structure:  $\cancel{O(m \log n)}$ .  
 ~~$m \log n = O(m \log n)$~~
- Parallel merge (Borůvka)
  - Starting from sets  $\{v\}$  for all  $v \in V$ , repeatedly find lightest cut edges for all components, add all edges
  - Takes  $\log_2 n$  iterations, (number of components is at least halved) in  $O(m)$ .
- Reverse delete (Kruskal)
  - Process edges in ~~non-increasing~~ decreasing cost, remove edges that do not disconnect the graph.
  - Check can be done in  $\cancel{O(\log n (\log \log n)^3)}$  (Thorup 2000).

set of components

~~$2m \text{ find } O(n) \text{ union } O(1)$~~

$O(m \log n)$

$\leq 3$

~~$m \log n + m \log n (\log \log n)$~~
