Image-Based Modeling

- Construction of geometric models from images
- Exploiting object features (parallelism, symmetry)
- Better results for architectural models
- Main approaches
 - Projective geometry
 - Non-linear optimization
- Computer vision

Image-Based Modeling, Rendering and Lighting

Image-Based Rendering

- Rendering from samples (no explicit geometric model)
- Reduces the amount of work required to model a scene
- Decouples rendering time from scene complexity
- Uses shading from the original images
- Produces realistic renderings

Image-Based Modeling, Rendering and Lighting

Image-Based Lighting

- Illuminating scenes and objects (real or synthetic) with images of light from the real world
- Can produce very realistic renderings
- Basic Steps
 - Capture real-world illumination as omnidirectional, high-dynamic range images
 - Map the illumination onto a representation of the environment
 - Place the 3D objects in the environment

Rendering from Panoramas

- Panoramas are usually acquired using special cameras or created by stitching several pictures together
- Most common: cylindrical panoramas (360° horizontal)
- Distortions are compensated for during the rendering

Cylindrical Panoramas

- Planar images reprojected from the cylindrical ones
- Scene can be explored by panning and tilting
- Results are correct only from the original viewpoint
- Warping function
 - scaling the columns of the cylindrical image
 - can be implemented using an inverse formulation

Spherical Panoramas (cont.)

- Created stitching images acquired using
 - ultra-wide angle fisheye lens to capture at least 180° vertically
 - a parabolic mirror
 - more than one row of pictures

Images by Helmut Dersch: <http://www.panoguide.com/technique/spherical.html>

Plenoptic Stitching [Aliaga01]

- Supports exploration of unobstructed environments of arbitrary sizes and shapes
- Captures omnidirectional (360°) images over a grid
- Intersects the paths and creates image loops

Images courtesy of Daniel Aliaga, Bell Labs.

Modeling Pixel Color Changes Directly

$$L(u, v; l_u, l_v) = a_0 l_u^2 + a_1 l_v^2 + a_2 l_u l_v + a_3 l_u + a_4 l_v + a_5$$

Image-Based Modeling, Rendering and Lighting

Modeling Pixel Color Changes Directly

$$L(u, v; l_u, l_v) = a_0 l_u^2 + a_1 l_v^2 + a_2 l_u l_v + a_3 l_u + a_4 l_v + a_5$$

Polynomial Texture Mapping

PTM: Store RGB per pixel and
Store polynomial coefficients
(a_0 - a_5) per texel:

$$L(u, v; l_u, l_v) = a_0 l_u^2 + a_1 l_v^2 + a_2 l_u l_v + a_3 l_u + a_4 l_v + a_5$$

Why Polynomials?

- Compact Representation
- Consist solely of multiplies and adds.
- Cheap to evaluate on both modern CPUs and VLSI

$$\begin{aligned} R &= L \cdot R' \\ G &= L \cdot G' \\ B &= L \cdot B' \end{aligned}$$

Light Direction Parameterization

$$L(u, v; l_u, l_v) = a_0 l_u^2 + a_1 l_v^2 + a_2 l_u l_v + a_3 l_u + a_4 l_v + a_5$$

u, v - texture coordinates

a_0 - a_5 - fitted coefficients stored in texture map

l_u, l_v - projection of light direction into texture plane

* l_u, l_v can be
scan-converted
without normalization

Fitting PTMs to Image Data

- Given N light sources we compute the best fit for (a_0 - a_5) in the L_2 norm using S.V.D.
- SVD computed once for a given lighting arrangement

$$\begin{bmatrix} l_{u0}^2 & l_{v0}^2 & l_{u0}l_{v0} & l_{u0} & l_{v0} & 1 \\ l_{u1}^2 & l_{v1}^2 & l_{u1}l_{v1} & l_{u1} & l_{v1} & 1 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ l_{uN-1}^2 & l_{vN-1}^2 & l_{uN-1}l_{vN-1} & l_{uN-1} & l_{vN-1} & 1 \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ a_2 \\ a_3 \\ a_4 \\ a_5 \end{bmatrix} = \begin{bmatrix} L_0 \\ L_1 \\ \vdots \\ L_{N-1} \end{bmatrix}$$

Image-Based Modeling, Rendering and Lighting

PTM Fitting Errors

- Smoothing is not spatial, it occurs in light space.
- High spatial frequencies are well preserved.
- Hard shadows become softer.
- Point lights become area lights.
